Trace forms over finite fields of characteristic 2 with prescribed invariants

Robert W. Fitzgerald

Abstract

Set $F = \mathbf{F_2}$ and $K = \mathbf{F_{2^k}}$. Let

$$R(x) = \sum_{i=0}^{m} \epsilon_i x^{2^i},$$

with each $\epsilon_i \in \{0, 1\}$. Our trace forms are the quadratic forms $Q_R^K : K \to F$ given by $Q_R^K(x) = \mathrm{tr}_{K/F}(xR(x))$. These trace forms have appeared in a variety of contexts. They have been used to compute weight enumerators of certain binary codes [1, 2], to construct curves with many rational points and the associated trace codes [5], as part of an authentication scheme [3], and to construct certain binary sequences in [7, 8, 6].

In each of these applications one wants the number of solutions (in K) to $Q_R^K(x) = 0$, denoted by $N(Q_R^K)$. This is easily worked out (see [10], 6.26,6.32) in terms of the standard classification of quadratic forms:

$$N(Q_R^K) = \tfrac{1}{2}(2^k + \Lambda(Q_R^K)\sqrt{2^{k+r(Q_R^K)}}), \tag{1}$$

where $r(Q_R^K) = \dim \mathrm{rad}(Q_R^K)$ and

$$\Lambda(Q_R^K) = \begin{cases} 0, & \text{if } Q_R^K \simeq z^2 + \sum_{i=1}^{v} x_i y_i \\ 1, & \text{if } Q_R^K \simeq \sum_{i=1}^{v} x_i y_i \\ -1, & \text{if } Q_R^K \simeq x_1^2 + y_1^2 + \sum_{i=1}^{v} x_i y_i. \end{cases}$$

However, given R and K, there is no simple way to determine the invariants $r(Q_R^K)$ and $\Lambda(Q_R^K)$. The only known results cover the case of one-term

R [8] and two-term R [4]. Here we solve the inverse problem: Given K, determine all possible pairs of invariants (r, Λ) and construct the R with these invariants. We use this to construct new maximal Artin-Schreier curves.

1 General Results

We fix the notation. When R is fixed, we write $r(k)$ for $\dim \operatorname{rad}(Q_R^K)$ and $\Lambda(k)$ for $\Lambda(Q_R^K)$. For a linearized polynomial $L(x) = \sum a_i x^{2^i}$ over K, we set $L_{dn}(x) = \sum a_i x^i$. And for a polynomial $\ell(x) = \sum a_i x^i$ over K, we set $\ell_{up}(x) = \sum a_i x^{2^i}$.

Given $R(x) = \sum_{i=0}^{h} a_i x^{2^i}$, we set

$$R^*(x) = \sum_{i=1}^{h} a_i (x^{2^{h+i}} + x^{2^{h-i}}).$$

Note that $(R^*)_{dn}(1) = 0$. Set $f^{(r)}(x) = x^d f(1/x)$, where $d = \deg f$. Then f is self-reciprocal iff $f(x) = f^{(r)}(x)$.

Let d be odd. We need to distinguish two cases. We say d is in Case 1 when -1 is a power of 2 modulo d. We write $\eta(d) = 1$ to indicate Case 1 and let $w(d)$ be the least positive integer with $2^w \equiv -1 \pmod{d}$. We say d is in Case 2 when -1 is not a power of 2 modulo d. We write $\eta(d) = 0$ to indicate Case 2 and let $w(d)$ be the least positive integer with $2^w \equiv 1 \pmod{d}$. Note that

$$2^{w(d)} \equiv (-1)^{\eta(d)} \pmod{d}$$

in either case.

We summarize the known results on factors of $x^k + 1$.

Lemma 1.1. *1. If $k = tn$ where t is a 2-power and n is odd then $x^k + 1 = \prod_{d|n} Q_d(x)^t$, where Q_d is the cyclotomic polynomial of order d.*

2. Let d be odd. Set $\nu(d) = \varphi(d)/(2w(d))$.

(a) In Case 1, $Q_d(x)$ factors as a product of $\nu(d)$ many (distinct) irreducible, self-reciprocal polynomials of degree $2w(d)$.

(b) *In Case 2, $Q_d(x)$ factors as a product of $\nu(d)$ many (distinct) pairs $f(x)f^{(r)}(x)$, where $f(x)$ is irreducible, degree $w(d)$, and not self-reciprocal.*

Proof: (1) follows from $x^k+1=(x^n+1)^t$ and (2) follows from [13]. □

We will use the term *self-reciprocal factor* of $Q_d(x)$, d odd, to mean irreducible, self-reciprocal factors in Case 1 and pairs $f(x)f^{(r)}(x)$ with $f(x)$ irreducible in Case 2. Thus, in either case, $Q_d(x)$ is a product of $\nu(d)$ many (distinct) self-reciprocal factors of degree $2w(d)$.

The key result is:

Proposition 1.2. $\dim rad(Q_R^K) = \deg(x^k+1,(R^*)_{dn}(x))$.

Proof: Now $\alpha \in \mathrm{rad}(Q_R^K)$ iff $\alpha \in K$ and $R^*(\alpha)=0$ by [6] Lemma 8. Since the roots of $x^{2^k}+x$ are distinct, we have

$$\begin{aligned} |\mathrm{rad}(Q_R^K)| &= \deg(x^{2^k}+x, R^*(x)) \\ &= \deg(x^k+1,(R^*)_{dn}(x))_{up} \\ &= 2^{\deg(x^k+1,(R^*)_{dn}(x))}. \end{aligned}$$

We have used that for linearized L_1 and L_2 that $(L_1,L_2)=((L_1)_{dn},(L_2)_{dn})_{up}$, by [10], p. 111. Hence the result follows. □

The following is a substantial improvement over [4] Theorem 3.3.

Theorem 1.3. *Write $k=tn$ with t a 2-power and n odd. Set $T=\mathbf{F}_{2^t}$ and $D=\{d : d|n, d>1\}$. Then:*

1. *$r(Q_R^K)=s_1+\sum_{d\in D} 2s_d w(d)$ for some s_d such that*
   (a) *if $t=1$ then $s_1=1$;*
   (b) *if $t>1$ then s_1 is even and $0<s_1\le t$;*
   (c) *for $d\in D$, $0\le s_d\le t\nu(d)$.*
2. *$\Lambda(Q_R^K) = (-1)^{\sum_D s_d\eta(d)} \left(\frac{2}{n}\right)^t \Lambda(Q_R^T)$. Here $\left(\frac{2}{n}\right)$ is the Jacobi symbol, detecting whether or not 2 is a square modulo n.*

Proof: (1) If irreducible f divides $(R^*)_{dn}$ then so does $f^{(r)}$ since $(R^*)_{dn}$ is self-reciprocal. Hence Lemma 1.1 yields:

$$(x^k+1,(R^*)_{dn}) = (x+1)^{s_1}\prod_{d\in D}\prod_{i=1}^{\nu(d)} g_i^d(x)^{u_i(d)},$$

where the g_i^d are the self-reciprocal factors of Q_d and $0 \le u_i(d) \le t$. Set $s_d = \sum_{i=1}^{\nu(d)} u_i(d)$. Note that $0 \le s_d \le t\nu(d)$. Then 1.2 gives

$$r(Q_R^K) = s_1 + \sum_{d \in D} s_d \cdot 2w(d).$$

We check the bounds on s_1. First, $(R^*)_{dn}$ and $x^k + 1$ are both divisible by $x+1$ so that $s_1 \ge 1$. And $s_1 \le t$ as t is the highest power of $x+1$ dividing x^k+1. If $t = 1$ then $s_1 = 1$. Suppose $t > 1$. Suppose, by way of contradiction, that s_1 is odd. In particular, $s_1 < t$ so that $(x+1)^{s_1+1}$ divides $x^k+1 = (x^n+1)^t$. Write $(R^*)_{dn} = h(x)\cdot(x^k+1, (R^*)_{dn})$ for some $h(x)$. Then $h(x)$ is self-reciprocal and $\deg h(x)$ is odd. Then $h(1) = 0$ and so $(x+1)^{s_1+1}$ also divides $(R^*)_{dn}$, contrary to the assumption that s_1 is the highest power of $x+1$ dividing both x^k+1 and $(R^*)_{dn}$. Hence s_1 is even.

(2) Let p be an odd prime dividing n. Write $n = p^\ell m$ where $(p, m) = 1$. Note that $k = p^\ell tm$. Set

$$\begin{aligned} D_0 &= \{d \in D : p | d\} \\ D_1 &= \{d \in D : p \nmid d\} = \{\text{divisors } d > 1 \text{ of } m\}. \end{aligned}$$

For $E = \mathbf{F}_{2^e}$ recall that we write $r(e)$ for $r(Q_R^E)$ and $\Lambda(e)$ for $\Lambda(Q_R^E)$. By [4] Theorem 3.1,

$$\Lambda(k) 2^{\frac{1}{2}(r(k)-r(tm))} \equiv \left(\frac{2}{p^\ell}\right)^t \Lambda(tm) \pmod p.$$

As $x^{tm}+1$ divides x^k+1, we have

$$(x^m+1, (R^*)_{dn}) = (x+1)^{s_1} \prod_{d \in D_1} \prod_{i=1}^{\nu(d)} g_i^d(x)^{u_i(x)},$$

for the same s_1 and $u_i(d)$ as before. So

$$\begin{aligned} r(m) &= s_1 + \sum_{d \in D_1} s_d \cdot 2w(d) \\ r(k) - r(m) &= \sum_{d \in D_0} s_d \cdot 2w(d) \\ 2^{\frac{1}{2}(r(k)-r(m))} &= 2^{\sum_{D_0} s_d w(d)} \equiv (-1)^{\sum_{D_0} s_d \eta(d)} \pmod p, \end{aligned}$$

as p divides each $d \in D_0$. Then

$$\Lambda(k) = \left(\frac{2}{p^\ell}\right)^t (-1)^{\sum_{D_0} s_d \eta(d)} \Lambda(tm).$$

A simple induction argument completes the proof. □

The proof of 1.3 shows that every possible pair of invariants (r, Λ) does in fact arise. We record this as:

Corollary 1.4. *Write $d = tn$ as before. Suppose s_1 and $s_d, d \in D$ satisfy the conditions of Theorem 1.3. Then $r(Q_R^K) = s_1 + \sum_D 2s_d w(d)$ iff*

$$(R^*)_{dn} = h(x)(x+1)^{s_1} \prod_{d \in D} \prod_{i=1}^{\nu(d)} g_i^d(x)^{u_i(d)},$$

where the g_i^d are self-reciprocal factors of $Q_d(x)$, $s_d = \sum_{i=1}^{\nu(d)} u_i(d)$ and $h(x)$ is self-reciprocal and prime to $(x^k+1)/(\prod_D \prod g_i^d(x)^{u_i(d)})$.

We note that if the coefficients, a_i, of R are allowed to take on any value in K then every quadratic form over K arises as a Q_R^K (for some R) [5] Proposition 1.1, and so all invariant pairs are possible. Thus 1.3 gives the restrictions on the quadratic forms Q_R^K that follow from restricting the coefficients to $0, 1$.

2 When k is prime

Example 2.1. Suppose $k = 43$. Here we are in Case 1, $w(k) = 7$ and 2 is not a square modulo k. Say $R(1) = 0$ so that $\Lambda(1) = 1$ (see [4] Corollary 3.4). The possible values of $(r(Q_R^K), \Lambda(Q_R^K))$ are:

$$(1, -1) \qquad (15, +1) \qquad (29, -1) \qquad (43, +1).$$

We construct all $R(x)$ of degree 2^9 with $r(Q_R^K) = 15$ and $\Lambda(Q_R^K) = +1$. First, $x^{43} + 1 = (x+1)f_1 f_2 f_3$ where

$$\begin{aligned} f_1 &= x^{14} + x^{13} + x^{11} + x^7 + x^3 + x + 1 \\ f_2 &= x^{14} + x^{12} + x^{10} + x^7 + x^4 + x^2 + 1 \\ f_3 &= x^{14} + x^{11} + x^{10} + x^9 + x^8 + x^7 + x^6 + x^5 + x^4 + x^3 + 1. \end{aligned}$$

Then $(R^*)_{dn} = h(x)f_i$ for some i and some self-reciprocal h of degree 4 with $h(1) = 0$. There are only two choices for h, namely, $h_1 = x^4 + 1$ and $h_2 = x^4 + x^3 + x^2 + x + 1$. So there are six choices for $(R^*)_{dn}$. Note that R and $R + x$ yield the same R^*, so we take whichever of R, $R + x$ satisfies $R(1) = 0$. We obtain:

$(R^*)_{dn}$	R
$h_1 f_1$	$x^{2^9} + x^{2^6} + x^{2^4} + x^{2^3}$
$h_2 f_1$	$x^{2^9} + x^{2^8} + x^{2^5} + x^{2^3}$
$h_1 f_2$	$x^{2^9} + x^{2^8} + x^{2^6} + x^{2^5} + x^{2^4} + x$
$h_2 f_2$	$x^{2^9} + x^{2^7} + x^{2^5} + x^{2^4} + x^{2^3} + x^2$
$h_1 f_3$	$x^{2^9} + x^{2^7} + x^{2^3} + x^{2^2} + x^2 + x$
$h_2 f_3$	$x^{2^9} + x^{2^8} + x^{2^7} + x^{2^3}$.

The goal of this section is to imitate the example and count the number of R with a given pair of invariants (r, Λ).

Lemma 2.2. *Let d be even. Let $f(x) \in F[x]$ be self-reciprocal of degree d and satisfy $f(1) = 1$. Let $N > d$ be even. The number of self-reciprocal $g(x) \in F[x]$ which are multiples of f, degree N and satisfy $g(1) = 0$ is $2^{\frac{1}{2}(N-d)-1}$.*

Proof: Write $g(x) = h(x)f(x)$. We require that $h(x)$ be self-reciprocal, degree $N - d$ and have $h(1) = 0$. The last condition implies that $h(x)$ has no middle term (that is, $x^{(N-d)/2}$). Thus $h(x)$ is determined by the coefficients of x^i, $1 \leq i < \frac{1}{2}(N - d)$, giving the result. □

Lemma 2.3. *Let $f_1, f_2, \ldots, f_t$ be pairwise prime, self-reciprocal polynomials in $F[x]$ of even degree d that satisfy $f_i(1) = 1$. Let N be even and set*

$$\ell = \min\left\{ \left\lceil \frac{N}{d} \right\rceil - 1, t \right\}.$$

The number of self-reciprocal $h(x) \in F[x]$ of degree N, prime to $f_1 \cdot f_2 \cdot \cdots \cdot f_t$ and satisfying $h(1) = 0$ is:

$$\sum_{m=0}^{\ell} (-1)^m \binom{t}{m} 2^{\frac{1}{2}(N-dm)-1}.$$

Proof: Let $M(f)$ denote the set of self-reciprocal polynomials $h(x) \in F[x]$ of degree N with $h(1) = 0$ and $f|h$. Let

$$M(f_{i_1}, f_{i_2}, \ldots, f_{i_m}) = \bigcap_{j=1}^{m} M(f_{i_j}),$$

where $m \le t$. If $N \le dm$ then $M(f_{i_1}, \ldots, f_{i_m}) = \emptyset$ (if $N = dm$ then we must have $h(1) = 1$), Otherwise, $dm < N$ so that $m \le \ell$. Apply 2.2 to $f = f_{i_1} \cdot f_{i_2} \cdots f_{i_m}$ to get

$$|M(f_{i-1}, f_{i_2}, \ldots, f_{i_m})| = \begin{cases} 2^{\frac{1}{2}(N-dm)-1}, & \text{if } m \le \ell \\ 0, & \text{if } m > \ell. \end{cases}$$

The total number of self-reciprocal $h(x)$ of degree N with $h(1) = 0$ is $2^{\frac{1}{2}N-1}$. So the number of $h(x)$ of the statement is:

$$\begin{aligned} 2^{\frac{1}{2}N-} - |\bigcup_{i=1}^{t} M(f_i)| &= 2^{\frac{1}{2}N-1} - \sum_{m=1}^{t} \sum_{i_1 < \cdots i_m} |M(f_{i_1}, \ldots, f_{i_m})| \\ &= 2^{\frac{1}{2}N-1} - \sum_{m=1}^{\ell} (-1)^{m+1} \binom{t}{m} 2^{\frac{1}{2}(N-dm)-1} \\ &= \sum_{m=0}^{\ell} (-1)^m \binom{t}{m} 2^{\frac{1}{2}(N-dm)-1}. \end{aligned}$$

□

We continue to write $\nu(k)$ for $\varphi(k)/(2w(k))$.

Theorem 2.4. *Let k be a prime. For any R:*

1. $\dim rad(Q_R^K) = 1 + 2sw(k)$ *for some* $0 \le s \le v(k)$.
2. *If* $R(1) = 1$ *then* $\Lambda(Q_R^K) = 0$.
3. *If* $R(1) = 0$ *then* $\Lambda(Q_R^K) = (-1)^{s\eta(k)}(\frac{2}{k})$.
4. *The number of R of degree 2^N with $R(1) = 0$ and $\dim rad(Q_R^K) = 1 + 2sw(k)$ is:*

$$\binom{\nu(k)}{s} \sum_{m=0}^{\ell} (-1)^m \binom{\nu(k) - s}{m} 2^{N-w(k)(s+m)-1},$$

where

$$\ell = \min\left\{\left\lceil \frac{N}{w(k)} \right\rceil - s - 1, \nu(k) - s\right\}.$$

Proof: (1), (2) and (3) follow from Theorem 1.3. To prove (4), fix s. By Corollary 1.4, $(x^k+1,(R^*)_{dn})$ is $x+1$ times a product of s self-reciprocal factors of $Q_k(x)$, each of degree $2w(k)$. $Q_k(x)$ has $\nu(k)$ many self-reciprocal factors. Choose s of them, call their product g and let $f_1, f_2, \ldots, f_t$, $t = \nu(k) - s$, be the other self-reciprocal factors. Then $R^* = h(x)g(x)$ where $h(x)$ is self-reciprocal, $h(1) = 0$ (so that $x+1$ is a factor of R^*), of degree $2N - 2sw(k)$ (as $\deg R = 2^N$ iff $\deg R^* = 2N$) and $h(x)$ is prime to g. Given this choice of the s factors then Lemma 2.3 gives the number of such h's as:

$$\sum_{m=0}^{\ell} (-1)^m \binom{\nu(k)-s}{m} 2^{\frac{1}{2}(2N-2sw(k)-m\cdot 2w(k))-1},$$

where

$$\begin{aligned}\ell &= \min\left\{\left\lceil \frac{2N-2sw(k)}{2w(k)} \right\rceil - 1, \nu(k) - s\right\} \\ &= \min\left\{\left\lceil \frac{N}{w(k)} \right\rceil - s - 1, \nu(k) - s\right\}.\end{aligned}$$

Hence the number of R^* of degree 2^{2N} with $(x^k+1,(R^*)_{dn}) = (x+1)g(x)$ is:

$$\binom{\nu(k)}{s} \sum_{m=0}^{\ell} (-1)^m \binom{\nu(k)-s}{m} 2^{N-w(k)(s+m)-1}.$$

Both R and $R+x$ yield the same R^* and exactly one of $R, R+x$ maps 1 to 1. So the number of R with $R(1) = 1$ and $\dim \mathrm{rad}(Q_R^K) = 1 + 2sw(k)$ is given by the same formula. □

One may easily check the formula on Example 2.1. There $k = 43$, $w(k) = 7$ and so $\nu(k) = 3$. The example considered R of degree 2^9 and $r = 15$ (which is $s = 1$). Then $\ell = \min\{\lceil \frac{9}{7} - 1 - 1, 6 - 1\} = 0$ and the number of such R is: $\binom{3}{1}(-1)^0\binom{6-1}{0}2^{9-7-1} = 6$, which agrees with the example.

3 When k is a product of two primes

The values of $w(d)$, over divisors of k, are not independent. Thus the formulas for $\dim \mathrm{rad}(Q_R^K)$ and $\Lambda(Q_R^K)$ of Theorem 1.3 simplify. But the underlying number theory is complicated. We illustrate these points by considering the easy case of k being a product of two primes.

Lemma 3.1. *Let p be an odd prime and let $\epsilon = \pm 1$.*

1. *If $2^w \equiv \epsilon \pmod{p}$ then $2^{wp} \equiv \epsilon \pmod{p^2}$.*
2. *p^2 is in Case 1 iff p is.*
3. *$w(p^2) = w(p)$ or $pw(p)$.*

Proof: (1) We have:

$$2^{wp} - \epsilon = (2^w - \epsilon)(2^{w(p-1)} + \epsilon 2^{w(p-2)} + \cdots + \epsilon^{p-2} 2^w + \epsilon^{p-1}).$$

Modulo p, the second factor is $p\epsilon^{p-1}$. Thus p^2 divides $2^{wp} - \epsilon$.

(2) If p is in Case 1 then $2^w \equiv -1 \pmod{p}$ for some w. Then (1) shows p^2 is also in Case 1. And if p^2 is in Case 1 then $2^v \equiv -1 \pmod{p^2}$ for some v. So $2^v \equiv -1 \pmod{p}$ and p is in Case 1.

(3) We have $w(p) | w(p^2)$ and by (1), $w(p^2) | pw(p)$. □

Remark 3.2. It is possible for $w(p^2)$ to equal $w(p)$, but exceedingly rare. If $w(p^2) = w(p)$ then p is a Wieferich prime, meaning that $2^{p-1} \equiv 1 \pmod{p^2}$ (see [11]). A computer search [9] has shown that the only Wieferich primes less than 1.25×10^{15} are 1093 and 3511. Both 1093 and 3511 satisfy $w(p) = w(p^2)$ (this can easily be checked with a computer). Further, 1093 is in Case 1 (with $w(1093) = 182$) and 3511 is in Case 2 (with $w(3511) = 1755$).

A typical simplification of Theorem 1.3 is:

Corollary 3.3. *Let $k = p^2$, with p and odd prime that is not a Wieferich prime. Then*

$$\begin{aligned} \dim rad(Q_R^K) &= 1 + (2s_1 + 2ps_2)w(p) \\ \Lambda(Q_R^K) &= (-1)^{(s_1+s_2)\eta(p)}\Lambda(1). \end{aligned}$$

□

The simplification for Wieferich primes can also be easily worked out. In the next result, $v_2(n)$ denotes the highest power of 2 dividing n.

Proposition 3.4. *Let p and q be distinct odd primes.*

1. *pq is in Case 1 iff p and q are in Case 1 and also $v_2(w(p)) = v_2(w(q))$. In this case, $w(pq) = lcm(w(p), w(q))$.*

2. *If p and q are in Case 1 and $v_2(w(p)) \neq v_2(w(q))$ then $w(pq) = 2lcm(w(p), w(q))$.*

3. *If p is in Case 1 and q is in Case 2 then $w(pq) = lcm(2w(p), w(q))$.*

4. *If p and q are in Case 2 then $w(pq) = lcm(w(p), w(q))$.*

Proof: (1) Suppose pq is in Case 1. Then $2^{w(pq)}$ is -1 modulo pq, hence modulo p and q. So both p and q are in Case 1. We want to show that $v_2(w(p)) = v_2(w(q))$. Suppose instead that $v_2(w(p)) < v_2(w(q))$. Let $L = \text{lcm}(w(p), w(q))$; note that $L/w(p)$ is even. Now $w(p)$ and $w(q)$ divide $w(pq)$ so L divides $w(pq)$. Hence $w(pq)/w(p)$ is even. But $2^{w(pq)} = (2^{w(p)})^{w(pq)/w(p)} \equiv 1 \pmod p$ while $2^{w(pq)} \equiv -1 \pmod{pq}$, a contradiction. So $v_2(w(p)) = v_2(w(q))$.

Conversely, suppose p and q are in Case 1 and $v_2(w(p)) = v_2(w(q))$. Then $L/w(p)$ and $L/w(q)$ are odd. So 2^L is -1 modulo p and q, hence modulo pq. Thus pq is in Case 1. Note that $w(pq)|L$ and clearly $L|w(pq)$. So $w(pq) = \text{lcm}(w(p), w(q))$.

(2) Here pq is in Case 2 so that $w(pq)$ is the order of 2 modulo pq. As p and q are in Case 1, the order of 2 modulo p is $2w(p)$ and modulo q it is $2w(q)$. Hence $w(pq) = 2\text{lcm}(w(p), w(q))$. Parts (3) and (4) are similar. □

Examples (1) We consider $k = 11 \cdot 43$. We have $p = 11$ is in Case 1 (with $w(p) = 5$) and $q = 43$ is also in Case 1 (with $w(q) = 7$). Thus by (1) of Proposition 3.4 we have that k is in Case 1 and $w(k) = 35$. Theorem 1.3 becomes:

$$\begin{aligned} \dim \text{rad}(Q_R^K) &= 1 + 10s_1 + 14s_2 + 70s_3 \\ \Lambda(Q_R^K) &= (-1)^{s_1+s_2+s_3}\Lambda(1), \end{aligned}$$

where $0 \leq s_1 \leq 1$, $0 \leq s_2 \leq 3$ and $0 \leq s_3 \leq 6$. Each choice of s_i occurs for some R.

(2) The case $k = 21$ was considered in [4] where a computer search showed that $\dim \text{rad}(Q_R^K) = 5$ was not possible. We may now easily check this. Here $w(3) = 1$, $w(7) = 3$ and $w(21) = 6$. Hence $\dim \text{rad}(Q_R^K) = 1+2s_1+6s_2+12s_3$

with each $s_i \in \{0,1\}$. Thus 5,11 and 17 are precisely the odd values missed by $\dim \mathrm{rad}(Q_R^K)$.

(3) The value of $\dim \mathrm{rad}(Q_R^K)$ does not always determine $\Lambda(Q_R^K)$, even when $R(1) = 0$ (so that $\Lambda(1) = 1$). Consider $k = 19 \cdot 73$. Here $p = 19$ is in Case 1 with $w(p) = 9$ and 2 not a square modulo p. And $q = 73$ is in Case 2 with $w(q) = 9$ and 2 a square modulo q. So

$$\begin{aligned} \dim \mathrm{rad}(Q_R^K) &= 1 + 18s_1 + 18s_2 + 36s_3 \\ \Lambda(Q_R^K) &= (-1)^{s_1+1}\Lambda(1), \end{aligned}$$

where $0 \leq s_1 \leq 1$, $0 \leq s_2 \leq 4$ and $0 \leq s_3 \leq 36$. Then $\dim \mathrm{rad}(Q_R^K) = 19$ has two solutions, namely $(s_1, s_2, s_3) = (1,0,0)$ and $(0,1,0)$, that yield different values of $\Lambda(Q_R^K)$. We can construct specific examples using Corollary 1.4. We can take Q_{19} or $(x^9 + x + 1)(x^9 + x^8 + 1)$ (a self-reciprocal factor of Q_{73}) for $(x^k + 1, (R^*)_{dn})$. Assuming $R(1) = 0$ so that $\Lambda(1) = 1$, these yield

$$\begin{aligned} R_1 &= x^{2^{10}} + x^{2^9} \\ R_2 &= x^{2^{10}} + x^{2^9} + x^{2^8} + x^{2^7} + x^{2^2} + x^2. \end{aligned}$$

Both give radicals of dimension 19 but $\Lambda(Q_{R_1}^K) = +1$ while $\Lambda(Q_{R_2}^K) = -1$.

4 Maximal Artin-Schreier Curves

The Artin-Schreier curves considered here are:

$$C_R(K) : y^2 + y = xR(x),$$

where $x, y \in K$. This has genus $g = \frac{1}{2}\deg R(x)$ by [12] VI.4.1. The number of points in K-projective space on C_R is:

$$\#C_R(K) = 2N(Q_R^K) + 1 = 2^k + 1 + \Lambda(Q_R^K)\sqrt{2^{k+r}},$$

where $r = \dim \mathrm{rad}(Q_R^K)$ and we have used Equation 1. The curve is *maximal* if equality holds in the Hasse-Weil bound

$$\#C_R(K) \leq 2^k + 1 + 2g\sqrt{2^k} = 2^k + 1 + \deg R(x)\sqrt{2^k}.$$

Clearly equality holds only if k is even. Maximal curves yield the best algebraic geometry codes.

Lemma 4.1. *Let k be even and $r = \dim rad(Q_R^K)$. Then $C_R(K)$ is maximal iff*

1. $\deg R(x) = 2^{r/2}$ *and*
2. $\Lambda(Q_R^K) = +1$.

Proof: We require $\Lambda(Q_r^K)\sqrt{2^{k+r}} = \deg R(x)\sqrt{k}$, which yields the result. □

In [5] we found all R and K with $C_R(K)$ maximal and $k - r = 2$ (note: the codimension $k - r$ is necessarily even). We also gave one example, found by computer search, of a maximal $C_R(K)$ with $k - r = 4$. As Lemma 4.1 prescribes the invariants of Q_R^K, we may now find all codimension 4 maximal curves, at least for a wide range of k.

As k must be even, Theorem 1.3 reduces the computation of $\Lambda(Q_R^K)$ to that of $\Lambda(Q_R^T)$ where $T = \mathbf{F}_{2^t}$ for t, the highest 2-power dividing k. We have been unable to do this in general, hence our restrictions on k.

Define

$$\begin{array}{lrcl} \text{for } 0 \le i \le 1 & S_i & = & \text{number of } \epsilon_j = 1 \text{ with } j \equiv i \pmod 2 \\ \text{for } 0 \le i \le 3 & T_i & = & \text{number of } \epsilon_j = 1 \text{ with } j \equiv i \pmod 4). \end{array}$$

Lemma 4.2. *1. Suppose $K = \mathbf{F_4}$. Then:*

$$\Lambda(Q_R^K) = \begin{cases} 0, & \text{if } S_0 \text{ is odd} \\ +1, & \text{if } S_0 \text{ is even.} \end{cases}$$

2. Suppose $K = \mathbf{F_{16}}$. Then:

$$\Lambda(Q_R^K) = \begin{cases} 0, & \text{if } T_0 \text{ is odd and } T_1 + T_3 \text{ is even} \\ +1, & \text{if } T_0 \equiv T_1 + T_3 \pmod 2 \\ -1, & T_0 \text{ is even and } T_1 + T_3 \text{ is odd.} \end{cases}$$

Proof: We check (2). If $x \in K$ then $x^{2^i} = x^{2^j}$ when $i \equiv j \pmod 4$. Hence, as a function on K, $R = T_0 x + T_1 x^2 + T_2 x^4 + T_3 x^8$. Further, $x^3 \in \mathbf{F_4}$ so that $\mathrm{tr}(x^3) = 0$ and

$$\mathrm{tr}(x^9) = \mathrm{tr}(x^{18}) = \mathrm{tr}(x^3).$$

Thus $Q_R(x) = \mathrm{tr}(T_0x^2 + (T_1 + T_3)x^3)$ for all $x \in K$. A simple computation shows that

$$N(Q_R^K) = \begin{cases} 4, & \text{if } T_0 \text{ even, } T_1 + T_3 \text{ odd} \\ 8, & \text{if } T_0 \text{ odd, } T_1 + T_3 \text{ even} \\ 12, & \text{if } T_0 \text{ odd, } T_1 + T_3 \text{ odd} \\ 16, & \text{if } T_0 \text{ even, } T_1 + T_3 \text{ even.} \end{cases}$$

Comparing with Equation 1 gives the result. The proof of (1) is similar and easier. □

Lemma 4.3. *Let $r = \dim rad(Q_R^K)$. If $C_R(K)$ is maximal with $k - r = 4$ then k is divisible by 3 or 8. Further, if k is divisible by 5 but not 8 then s_5 is its maximal value.*

Proof: Assume k is not divisible by 8. Write $k = tn$ with n odd and $t = 2$ or 4. By 1.3

$$k - 4 = s_1 + \sum_{d|n} 2s_d w(d), \tag{2}$$

with $s_1 \in \{2, t\}$ and $0 \le s_d \le t\nu(d)$. Note that the maximum values, $s_1 = t$ $s_d = t\nu(d)$, make the right side of Equation 2 equal to k. We are looking for a solution just below the maximum.

If $w(d) \le 2$ then d divides $2^2 \pm 1, 2 \pm 1$ and so $d = 3$ or 5. Thus if no d is 3 or 5 then every $w(d) > 2$ and there is no solution to Equation 2.

Suppose, if possible, that 3 does not divide k. Then $k = 5m$ for some even m. Write $m = 2m_0$. The only solution to Equation 2 is:

$$s_1 = t \quad s_5 = t - 1 \quad s_d = t\nu(d) \quad \text{for } d \ne 5.$$

This is also the only solution if s_5 is not maximal (whether or not 3 divides k). Our construction, Corollary 1.4, shows that

$$(x^k + 1, (R^*)_{dn}) = (x + 1)^t Q_5^{t-1} \prod_{d \ne 5} Q_d^t = (x^k + 1)/Q_5.$$

By Lemma 4.1, $\deg R = 2^{(k-4)/2}$ and so $\deg(R^*)_{dn} = k - 4$. Hence

$$R^* = \frac{x^k + 1}{Q_5} = \frac{(x + 1)(x^k + 1)}{x^5 + 1} = (x + 1)\sum_{i=0}^{m-1} x^{5i}.$$

And so

$$R = \epsilon x + \sum_{i=0}^{m_0-1} \left(x^{2^{5(m_0-i)-2}} + x^{2^{5(m_0-i)-3}} \right),$$

for $\epsilon \in \{0, 1\}$.

Lemma 4.1 gives $\Lambda(Q_R^K) = +1$ while Theorem 1.3 gives $\Lambda(Q_R^K) = -\Lambda(t)$. Hence $t = 4$ since, by Lemma 4.2, $\Lambda(2) \neq -1$. So Lemma 4.2 gives T_0 is even and $T_1 + T_3$ is odd. We have R explicitly so we compute the T_i, writing $m_0 = 4\ell + u$:

u	T_0	T_1	T_2	T_3
0	$2\ell + \epsilon$	2ℓ	2ℓ	2ℓ
1	$2\ell + \epsilon$	2ℓ	$2\ell + 1$	$2\ell + 1$
2	$2\ell + 1 + \epsilon$	2ℓ	$2\ell + 1$	$2\ell + 2$
3	$2\ell + 2 + \epsilon$	$2\ell + 1$	$2\ell + 1$	$2\ell + 2$

(3)

If $\epsilon = 1$ then only $u = 2$ gives T_0 even, but the $T_1 + T_3$ is even. Hence $\epsilon = 0$ and we must have u odd. But then $k = 5 \cdot 2m_0 = 5 \cdot 2(4\ell + u)$ is not divisible by $t = 4$, a contradiction. Hence k is divisible by 3. $\square$

Example 4.4. Lemma 4.3 can fail when $k - r = 6$. We use Corollary 1.4 to construct an example with $k = 20$. We need $r = 14 = s_1 + 4s_5$ so we take $s_1 = 2$ and $s_5 = 3$. Then

$$\begin{aligned} (x^k + 1, (R^*)_{dn}) &= (x+1)^2 Q_5^3 = (x^{10} + 1)(x^4 + x^3 + x^2 + x + 1) \\ R &= x^{2^7} + x^{2^6} + x^{2^5} + x^{2^4} + x^{2^3} + \epsilon x. \end{aligned}$$

As before, $\Lambda(Q_R^K) = -\Lambda(4)$ so that we require T_0 to be even and $T_1 + T_3$ to be odd. Thus taking $\epsilon = 1$ gives an example of a maximal curve with $k - r = 6$ and k not divisible by either 3 or 8.

Theorem 4.5. *Suppose k is even but not a multiple of 8. Let $r = \dim rad(Q_R^K)$. Then the maximal curves $C_R(K)$ with $k - r = 4$ are precisely:*

1. *$k = 6m$ with m odd and*

$$R = x^2 + \sum_{i=1}^{3(m-1)/2} \left(x^{2^{6i+1}} + x^{2^{6i-1}} \right).$$

2. *$k = 12m$ with m odd and*

$$R = x + \sum_{i=0}^{m-1} \left(x^{2^{6i+4}} + x^{2^{6i+2}} \right).$$

3. $k = 12m$ *with* m *odd and*

$$R = x + \sum_{i=0}^{m-1} \left(x^{2^{6i+4}} + x^{2^{6i+3}} + x^{2^{6i+2}} \right).$$

Proof: From Lemma 4.3 we have $k = 6m$ or $12m$ with m odd. We first do the case $k = 6m$. Equation 2 becomes:

$$k - 4 = 2 + 2s_3 + \sum_{d|3m, d \neq 3} 2s_d w(d),$$

for $0 \leq s_3 \leq 2$ and $0 \leq s_d \leq 2\nu(d)$. The only solution is $s_3 = 0$ and $s_d = 2\nu(d)$ for $d \neq 3$, since all $w(d) > 2$ except for $d = 5$ when s_5 is its maximal value 2 by Lemma 4.3. Thus

$$(x^k + 1, (R^*)_{dn}) = \frac{x^k + 1}{Q_3^2} = (x^2 + 1) \sum_{i=0}^{m-1} x^{6i}.$$

Lemma 4.1 gives $\deg R = 2^{(k-4)/2}$ and $\deg(R^*)_{dn} = k - 4$. Hence R^* is this gcd and

$$R = \epsilon x + \sum_{i=1}^{3(m-1)/2} \left(x^{2^{6i+1}} - x^{2^{6i-1}} \right).$$

Lastly, $\Lambda(Q_R^K) = +1$ by Lemma 4.1 while $\Lambda(Q_R^K) = \Lambda(2)$ by Theorem 1.3. Hence $\epsilon = 0$ by Lemma 4.2.

Now suppose $k = 12m$ with m odd. Equation 1 becomes:

$$k - 4 = s_1 + 2s_3 + \sum_{d|3m, d \neq 3} 2s_d w(d),$$

where $s_1 \in \{2, 4\}$, $0 \leq s_3 \leq 4$ and $0 \leq s_d \leq 4\nu(d)$. As before, each s_d, $d \neq 1, 3$, is its maximal value. So there are two solutions, $(s_1, s_3) = (4, 2)$ and $(2, 3)$. In the first case, $(R^*)_{dn} = (x^k + 1)/Q_3^2$ and R has the form (2). Here Lemma 4.2 is used to determine the coefficient of x. In the second case, $(R^*)_{dn} = (x^k + 1)/(x^6 + 1)$ and R has the form (3). □

We note that the example of [5] is statement (2) of Theorem 4.5 with $m = 1$.
